

Pupil Performance and Age

A Study of Promotion, Repetition, and Dropout Rates among Pupils in Four Age Groups in 35 Developing Countries

EPDC Working Paper No. EPDC-09-02

Winter 2009

Pupil Performance and Age

A Study of Promotion, Repetition, and Dropout Rates among Pupils in Four Age Groups in 35 Developing Countries ‡

ABSTRACT

In recent years, many school systems have increased gross intake rates and come closer to meeting Education for All goals. One side effect of this increase is larger numbers of overage pupils in primary and secondary school. This study uses household survey data from 35 countries to measure the extent and effects of school attendance by overage pupils. The study finds that in the lower grades of primary school, older pupils generally outperform younger ones. Younger pupils are far more likely to repeat grades than older pupils. There are particularly high repetition rates of underage pupils in first grade; these suggest there is an unmet need for kindergarten facilities. In higher grades of primary school and in all grades of secondary school, older pupils are less likely to be promoted and more likely to drop out of school, resulting in lower survival rates than those of younger pupils. The two most important policy implications of this study are: 1) the unmet need for education facilities for younger children should be met, and 2) there is need for special focus on older pupils in *higher* grades to ensure that they remain in school.

The **Education Policy and Data Center (EPDC)**, a partnership of FHI 360 and the US Agency for International Development, was founded in 2004 to contribute to better education policy making and planning through improved access to and use of data and analysis. For more information, see www.epdc.org.

‡ This report has been prepared by the Education Policy and Data Center (EPDC) from a series of studies commissioned by the GMR as background to the *2009 EFA Global Monitoring Report*.

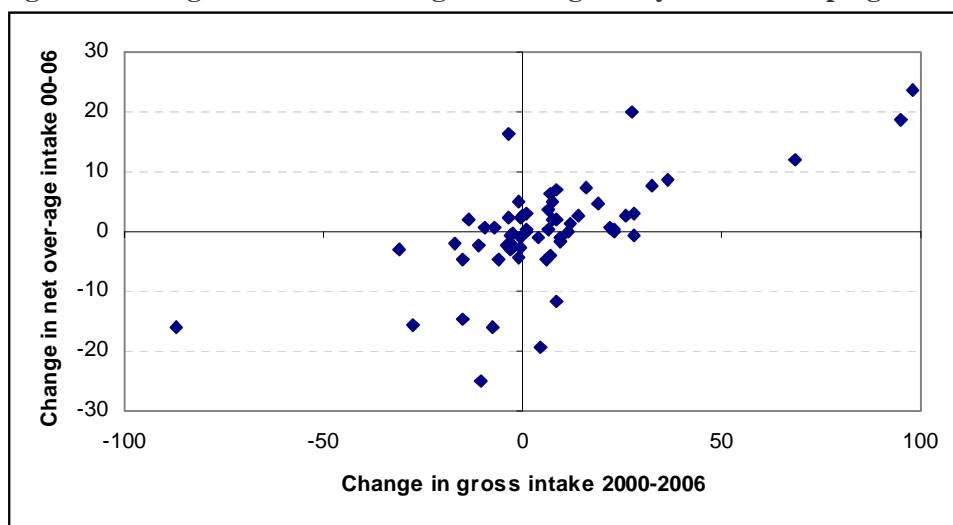

Working papers disseminated by the EPDC reflect ongoing research and have received limited review. Views or opinions expressed herein do not necessarily reflect the policy or views of FHI 360 or of any of the EPDC sponsors.

BACKGROUND

Over attendance is widespread in developing countries. According to one common measure of overage pupils, in 2005 in 20% of countries, more than 20% of primary pupils were overage. In fact, this number underestimates the extent of overage attendance because it only measures the proportion of children attending primary school who are older than the highest primary school age. It does not include the many children who are overage for their *grade* but still fall within the range of primary school children – all the

first graders who are 9, 10, and 11 years old, for example. Grade and age-specific data for 2004 from UIS show that in 40% of 74 developing countries with available data, 20%-61% of the pupils are registered as two or more years older than the official age for their grade. The EPDC background report to the GMR 2008 (EPDC, 2007b:58) shows that overage attendance increased in many Sub-Saharan African countries in the past decade, while it declined in countries in other regions.

Figure 1. Change in GIR and change in overage entry in 60 developing countries from 2000-2006.

In those countries where primary intake increased since 2000, it appears that overage school intake also increased, perhaps partly as a result. Figure 1 shows that there is some correlation between change in the gross intake rate (GIR) and the proportion of overage entrants from 1999-2006 in 60 developing countries. Thus, at least in some countries, the issue of overage students may be getting more pronounced.

Overage pupils are a group with unique needs. Overage pupils are more likely to be from disadvantaged groups (UNESCO, 2006:26), and

they also have different interests and responsibilities than their official-age peers. There is already some evidence to support the belief that overage pupils have higher repetition and drop-out rates than official age pupils (UNESCO, 2007:43; Cameron, 2005; Mendelson and Roberts, 1996; Wils, 2004).

Because the incidence of overage attendance is widespread, and because it is believed that overage pupils have higher than average repetition and drop-out rates, it is worth investigating impacts of pupil age on school performance more carefully.

DATA

The data for this study are from 35 Demographic and Health Surveys (DHS). The data from DHS surveys can be used to calculate promotion, repetition and dropout rates of pupils by their age. The surveys used are the most recent ones for which the datasets are available: all are post-2000 surveys. The majority (22) of the surveys represent countries in sub-Saharan Africa; six represent countries in Latin America; four are from Asia, two from Eastern Europe, and one from North Africa. Table 1 lists the datasets used in this study.

Measurement of pupils flows – promotion, repetition, and dropout

The calculation of pupil flows is based on a set of six questions in each DHS survey which, in tandem, can be used to determine the school levels and grades that a pupil attended over a two year period:

- Did you attend school in the previous school year?
 - What school level did you attend that year?
 - Within that level, what grade did you attend?
- Did/Are you attending school in the current school year
 - What school level are you attending?
 - Within that level, what grade are you attending?

This study analyzes pupils who were in school in the previous school year because it is only for these pupils that flows can be calculated. The flows—promotion, repetition and dropout—are calculated as follows:

Promotion rate grade X: Pupils who were attending grade X+1 or higher in the current year *and* who attended grade X in the previous year, divided by the pupils who were attending grade X in the previous year.

Repetition rate grade X: Pupils who were attending grade X or a lower grade² in the current year *and* who attended grade X in the previous year, divided by the pupils who were attending grade X in the previous year.

Dropout rate grade X: Children who were not attending school in the current year but *did* attend grade X in the previous year, divided by the pupils who attended grade X in the previous year. This is a broad definition of dropouts, and includes both 1) pupils who dropped out without completing the grade or level they most recently

² Pupils who repeat to a lower grade are believed to be a very rare observation, although the data extraction files were not written to count these cases.

attended, and 2) pupils who completed a grade or level but did not move on the next.³

With this definition, pupils who quit school at one of the transition grades, such as the end of primary, basic, mandatory, or lower secondary school, are counted as dropouts – peak dropout rates at these points indicate barriers that prevent pupils from moving on the next level. The study does not extend past the last grade of secondary; so all pupils who report having completed the last grade of secondary⁴ are classified as ‘promoted’.

Promotion rate last grade secondary school: Pupils who were attending the last grade of secondary school in the previous year and report currently having attained “complete secondary”, divided by the pupils who were attending the last grade of secondary school in the previous year.

Because the study analyzes the pupils who attended school in the previous year for each dataset, *New Entrants* to the school system in the present year are not considered in this study. A pupil would be classified as a new entrant if they reported not attending school in the previous year, but did attend school in current year.

Relative age groups

To categorize pupils into underage, on-time and overage groups, the concept of *relative age* is introduced. The *relative age* of pupils refers to how many years the pupils’ age departs from the official age for their grade. The official ages for each grade are based on UNESCO Institute for Statistics (UIS) definitions. Relative age groupings are designated as follows:

Underage: The pupil’s age for the previous year is lower than the official age for the grade they reported attending during the previous year.

On-time: The pupil’s age for the previous year is equal to the official age for the grade they reported attending during the previous year.

One year overage: The pupil’s age for the previous year is one year higher than the official age for grade they reported attending during the previous year.

2+ years overage: The pupil’s age for the previous year is two or more years higher than the official age for grade they reported attending during the previous year.

Note that this definition of overage is *overage for grade*, as opposed the definition of overage commonly used by UIS and GMR, where the overage pupils in primary are those who are older than the official primary school age range.

Correcting for over-estimation of age due to birthdays between the beginning of school year and interview date

A weakness of the data lies in the fact that DHS surveys do not include children’s actual birthdates. The DHS surveys ask for the household members’ age, in years, at the time of the survey. The DHS surveys do not ask for birth date or age in months because the respondent of the survey may not know exact birthdates. This means that, while it is possible to determine whether a pupil was of the appropriate age for the grade at the time of the interview, it is not possible to be sure if the pupil was of the appropriate age for the grade at the time that they entered the grade, which is problematic because it is the age at the beginning of the school year that is relevant in the classification of a pupil as underage, on-time, or overage. When there is a large interval between the beginning of the school year and the date that a pupil’s age is recorded, there is a greater likelihood that the pupil has had a birthday in the meantime. This could mean, for example, that an underage pupil might be falsely reported as on-time, that an on-time pupil might be falsely reported as one year overage, and so on.

³ For example, in a system where there are five grades of primary, a pupil who completed grade five and graduated from primary school, but did not move on to secondary, would be classified as a ‘dropout’ along with the pupil who withdrew after attending grade five for just one month.

⁴ From a different set of questions on educational attainment.

Table 2. Estimated percentage of pupils who were recorded as one year older (in number of birthdays) at the time of the survey than at the beginning of the school year.

Armenia	6%	Ethiopia	19%	Malawi	61%	Peru	40%
Benin	52%	Ghana	33%	Mali	41%	Philippines	8%
Burkina Faso	58%	Guinea	49%	Moldova	42%	Rwanda	66%
Cambodia	26%	Haiti	33%	Mozambique	77%	Senegal	46%
Cameroon	51%	Honduras	62%	Namibia	79%	Tanzania	58%
Colombia	39%	India	54%	Nepal	59%	Uganda	41%
Congo, Rep.	75%	Kenya	39%	Nicaragua	65%	Zambia	34%
Dominican Rep.	24%	Lesotho	68%	Niger	43%	Zimbabwe	54%
Egypt	66%	Madagascar	26%	Nigeria	69%		

The effect is that there is an upward bias in the reported age of pupils, leading to an overestimation of the proportion of pupils identified as too old for their grades. This effect is greater the longer the interval between the beginning of the school year and the survey interview. This effect will hereafter be called the *birthday effect*.

To correct for this *birthday effect*, it is possible to estimate the percentage of pupils who likely have had a birthday and are therefore recorded as one year older than they were at the beginning of the school year. The age of this percentage of pupils is then corrected downwards.

The percentage of pupils who had a birthday between the beginning of the school year and the interview is calculated as the *weighed probability of overestimation*. The calculation is based on the simple principle that, for each month elapsed between the beginning of the school year and the date of the survey interview, an additional 1/12 of the pupils probably had a birthday (disregarding slight fluctuations in birthdays by month). The estimated national percentage of pupils who had a birthday between the beginning of the school year and the interview is calculated as the weighted sum of the proportions of primary pupils who were interviewed each month multiplied by 1/12 * the number of months between the start of the school year and the interview⁵. The results are

given in Table 2. Survey interview dates and the duration of the school year for each country are noted in Annex 1. In just a little under half of the countries (17 of 35), *more than half* of the pupils had a birthday between the beginning of the school year and the interview. In the Mozambique and Namibia surveys, the proportion of pupils with an intervening birthday is close to 80%.

While it is possible to correct the distribution of pupils by relative age, it is more difficult to do the same for the calculation of pupil flow rates – promotion, repetition, and dropout. If age affects the promotion, repetition, and dropout rates – as the results below show – one would have to be able to distinguish *individual* pupils who have had a birthday from those who have not. But this is not possible; it is only feasible to calculate the average percentage of pupils who have had a birthday overall. That said, in most of the findings on flows, there appears to be a continuous effect of age, so the overall conclusions are unlikely to be affected.

The correction of relative age distribution of the pupils by transferring some of the pupils in each relative age group to the next youngest one uses the following formulae:

*Corrected % under age = recorded % under age + (recorded % on-time * % who had a birthday).*

*Corrected % on-time = recorded % on-time * (1-% who had birthday) + (recorded % one year overage * % who had a birthday)*

⁵ Taking into account the fact that some surveys spanned multiple school years.

*Corrected % one year overage = recorded % one year overage * (1-% who had birthday) +.5 * (recorded % 2+ years overage * % who had a birthday)*

*Corrected % 2+ years overage = recorded % one year overage * (1-.5*% who had birthday)*

Note that for correcting the 2+ years overage, only half of the pupils are counted as exactly 2 years overage – an educated guess of the proportion of pupils who are this age; the rest are counted as 3+ years overage pupils who do not change relative age groups regardless of when their birthdays occurred.

Defining school grades and levels

The DHS surveys ask for the level and grade of pupils who are attending school. In some surveys, the number of grades in a level according to the DHS dataset differs from the UIS definition. When this occurs, the UIS definition is used to define the grades and school level. If a school system has separate lower and upper secondary programs, these are classified together as ‘secondary.’ The age and grade intervals used in the study are listed in Annex 1.

PREVALENCE OF OVERAGE PUPILS

Distribution of pupils by relative age in primary and secondary school

Figure 2 shows the distribution of pupils in primary school and secondary school by relative age in four age categories – underage, on-time, one year overage, and 2+ years overage – arranged in order of the percentage of pupils who are 2+ years overage in primary school. The numbers are corrected for the birthday effect as discussed in the previous section. Although the graphs refer to primary and secondary school overall the relative age of pupils is still determined by age in relation to grade (as discussed above). Pupils who are on-time make up a minority of primary school pupils in most countries in the sample; there is a high prevalence of pupils who

are 2+ years over age, but also sizeable groups of underage and one year overage pupils.

The percentage of primary pupils who are 2+ years overage—the primary focus group of this study—ranges from 6% to 73%. Among the 35 countries included in the study, there are only 11 where the percentage of primary-level pupils 2+ years overage is lower than 25% -- Moldova, Egypt, Armenia, Peru, India, Niger, Zimbabwe, Colombia, Burkina Faso, Philippines, and Nicaragua. In five countries, pupils 2+ years overage account for more than half of the primary-level student body – Ghana, Uganda, Ethiopia, Cambodia, Haiti.

The bottom graph of Figure 2 shows the percentage of pupils by relative age group for secondary grades, arranged in the same order as for primary grades. Overall, there is a higher proportion of pupils overage for their grade at the secondary level than at the primary level.

At the secondary level, only six countries have less than 25% of secondary pupils 2+ years overage – Egypt, Moldova, Armenia, India, Peru, and Zimbabwe. In 12 of 35 countries, pupils 2+ years overage account for more than half of secondary pupils – Madagascar, Benin, Rwanda, Nepal, Guinea, Kenya, Mozambique, Dominican Republic, Ethiopia, Cambodia, Haiti.

In 28 of the 35 countries, the proportion of pupils who are 2+ years overage is higher in secondary school than in primary. Among those, in eight countries the difference is significant: between 10 and 18 percentage points. In seven countries, the percentages of pupils 2+ years overage are *lower* in secondary than in primary – Cambodia, Ethiopia, Ghana, Egypt, Armenia, India, Tanzania. Among these, Tanzania shows the most significant decline – 13 percentage points.

Figure 2. Percentage of pupils by relative age group, primary school (top graph) and secondary school (bottom graph).

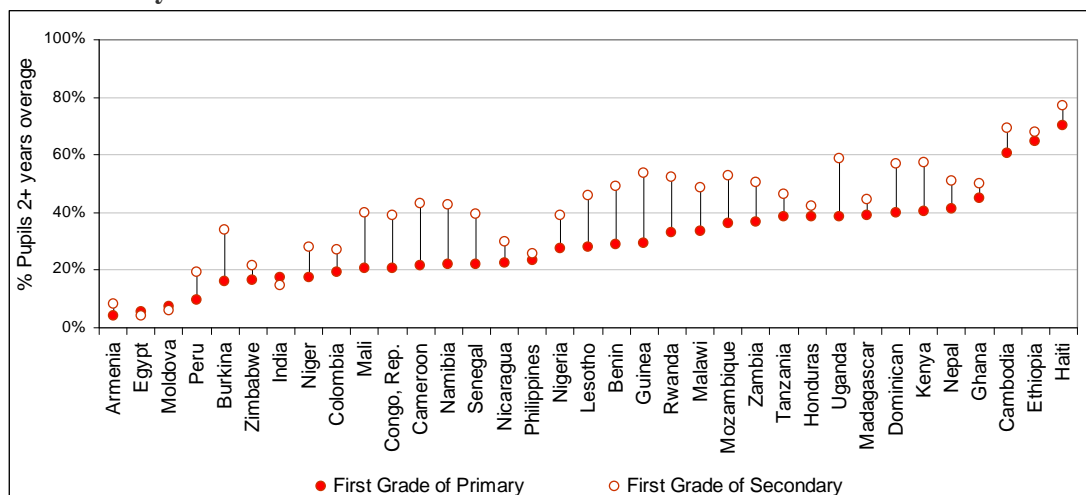

Proportion of pupils overage higher at start of secondary than at start of primary.

Another way to show that the proportion of pupils 2+ years overage is greater in higher grades is by comparing the proportions of pupils 2+ years overage in two grades. Figure 3 shows the proportions of pupils 2+ years overage in primary grade 1 and in the first grade of secondary school. Overall, the percentage of overage pupils increases over this grade interval (exceptions are: Egypt, Moldova, and India). In one-third (13 of 35) of the countries in the sample, the percentage of overage pupils increased by more than 10 percentage points

between the first grade of primary and the first grade of secondary.

It is likely that overage pupils become more prevalent in later grades as a result of high repetition rates—when a pupil repeats a grade, their age in the second year is one year higher than it was before. As a group, the repeaters contribute to an increase in the population of overage pupils. The prevalence of overage pupils can decline when overage pupils have relatively higher dropout rates. It appears that, in most countries, the effect of repetition is stronger than the effect of selective overage dropout.

Figure 3. Percentage of pupils 2+ years overage in the first grade of primary school and in the first grade of secondary school.

Comparison of the distribution of pupils by age from household surveys and from administrative data

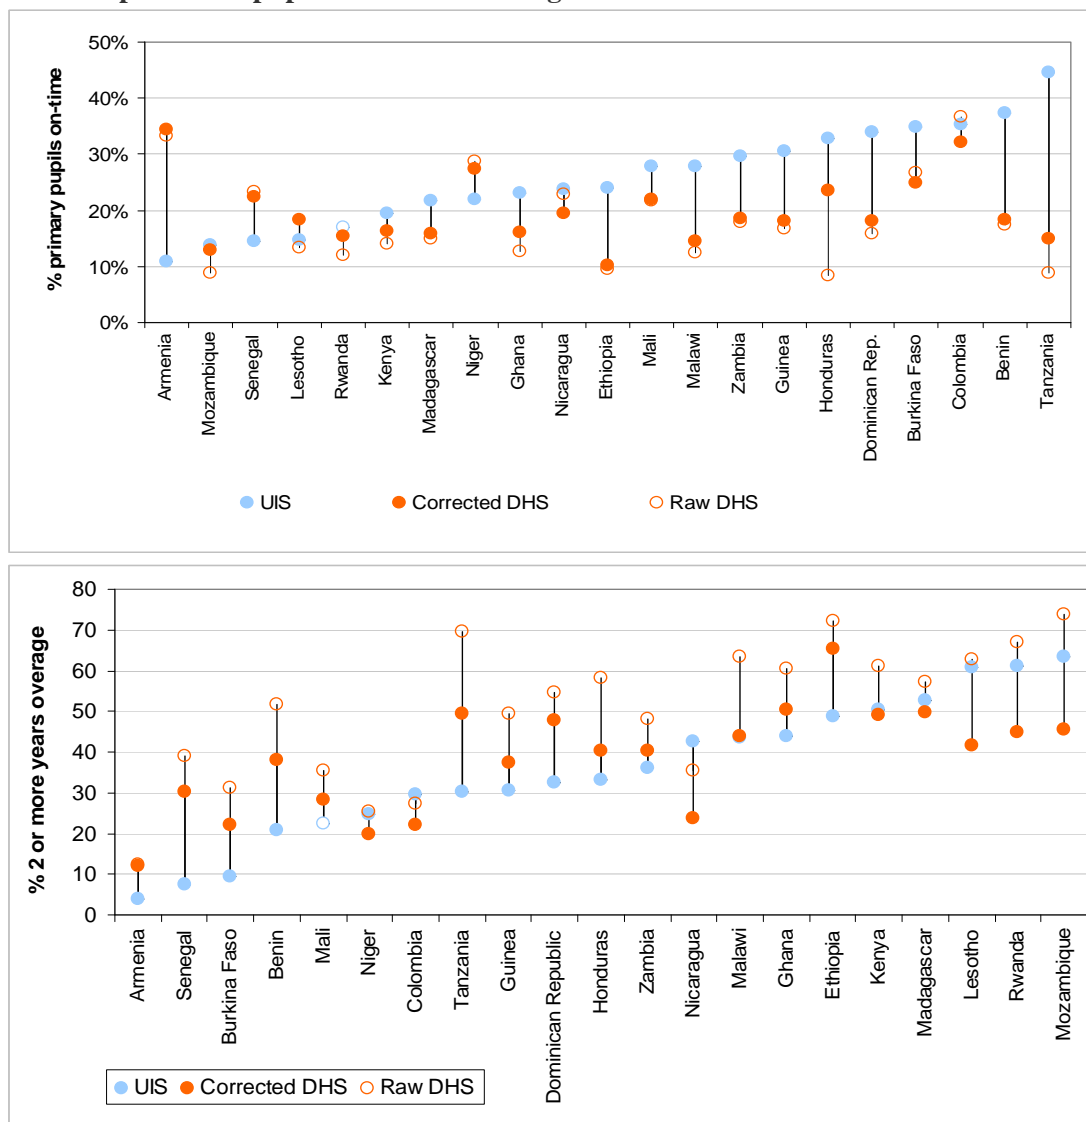

Attendance rates from household surveys often differ, at least slightly, from enrolment rates collected via administrative systems (see e.g. UNESCO, 2007; EPDC, 2007a). It is no different for the estimates of the distribution of pupils by relative age.

Figure 4 shows the percentage of on-time primary pupils and the percentage of pupils 2+ years overage for grade, in 22 countries, as calculated from 1) UIS data, 2) the DHS surveys corrected for birthdays, and 3) the uncorrected DHS survey data. Regarding the recording of pupils by age, the administrative data includes on-time pupils for all primary grades, but in some countries the overage pupils beyond a certain age are not counted, which could result in the proportion of overage pupils being underestimated.

It is clear from the figure that there are large differences between the two data types, whether using the raw DHS data for age groups or the DHS data corrected for birthdays. In fact, the correlation coefficients for the UIS on-time pupils with the raw DHS data and the corrected DHS data are $c=-.05$ and $c=-.02$ respectively.

For the percent overage pupils, the correlation coefficients are better: $c=.76$ for UIS and the raw DHS data and $c=.66$ for UIS and the corrected DHS data. It is not within the scope of this study to analyze the causes of these differences, but these discrepancies indicate that the results should be treated with caution. It is not possible to compare the flow rates by age—promotion, repetition and dropout—from household surveys and administrative data because the administrative data is not sufficiently detailed

Figure 4. Percentage of primary pupils who are on time (top graph) and who are 2+ years overage (bottom graph), according to administrative data from UIS, corrected DHS data and raw DHS data in order of the percent of pupils on time according to UIS data.

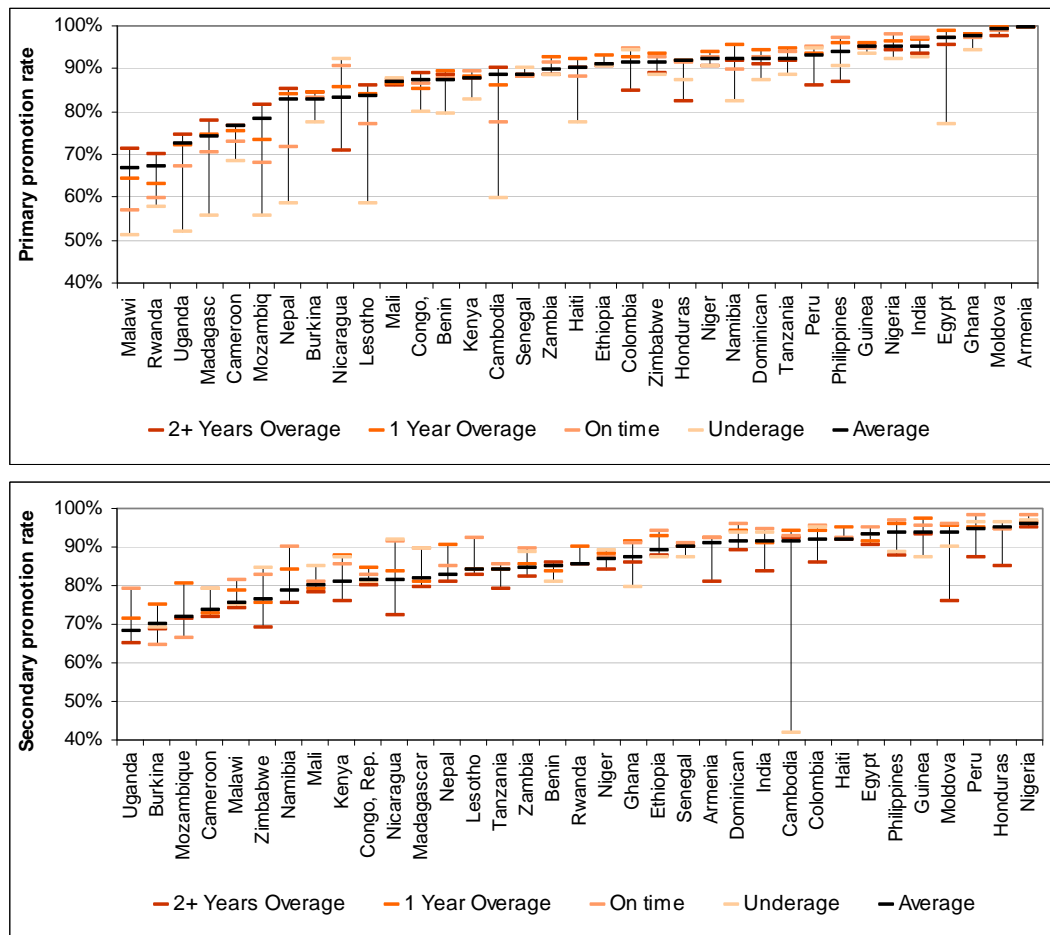

EFFICIENCY RATES—PROMOTION, SURVIVAL REPETITION AND DROPOUT—FOR OVERAGE PUPILS AS COMPARED TO ON-TIME AND UNDERAGE PUPILS

This section reviews the efficiency—promotion, survival, repetition and dropout—rates for overage pupils compared to on-time and underage pupils. For the efficiency flows the DHS data cannot be corrected for birthdays,

because it is not possible to distinguish children who have had birthdays from those who have not (it is only possible to calculate an overall probability of having had a birthday).

In summary, the data show that overage pupils do not progress through the school system with the same efficiency as their on-time or underage peers, but they do not necessarily fare any worse, at least in the earlier grades. At the primary level, promotion rates for pupils 2+

Figure 5. Promotion rates by relative age group in primary (top graph) and secondary (bottom graph).

years overage are equal to⁶ or greater than those of on-time pupils in 24 of the 35 countries sampled. At the secondary level however, pupils 2+ years overage do less well; promotion rates for pupils 2+ years overage are lower than those of on-time pupils in 29 out of the 35 countries.

The survival rates to grade 5 are similar for on-time and one year overage pupils; and somewhat lower for the pupils 2+ years overage. By the middle of secondary school, the differences in survival rates by relative age have widened considerably; there is a gap between on-time and pupils just one year overage, and a wider gap between these two groups and the pupils who are 2+ years overage. This pattern is consistent across countries.

When not promoted, pupils one and 2+ years overage are more likely to drop out than are underage or on-time pupils. In particular, at the last grade of primary school and in secondary grades, older pupils are far more likely to drop out of school than on-time or underage pupils.

Promotion at the primary and secondary levels

Figure 5 shows the average primary and secondary promotion rates for pupils by relative age group, arranged by the overall promotion rates. There are five lines for each country in each graph: a black one for average promotion rates; orange lines (from dark to light hues) for 2+ years overage, one year overage, on-time, and underage. Countries are arranged in

⁶ 'Equal' is defined conservatively as \pm two percentage points.

ascending order of average promotion. The graphs show that promotion rates vary between countries, but also that the promotion rates of the relative age groups differ in a number of countries. Note the scale on the graphs is from 40%-100% because there are no relative age groups in any countries with promotion rates below 40%.

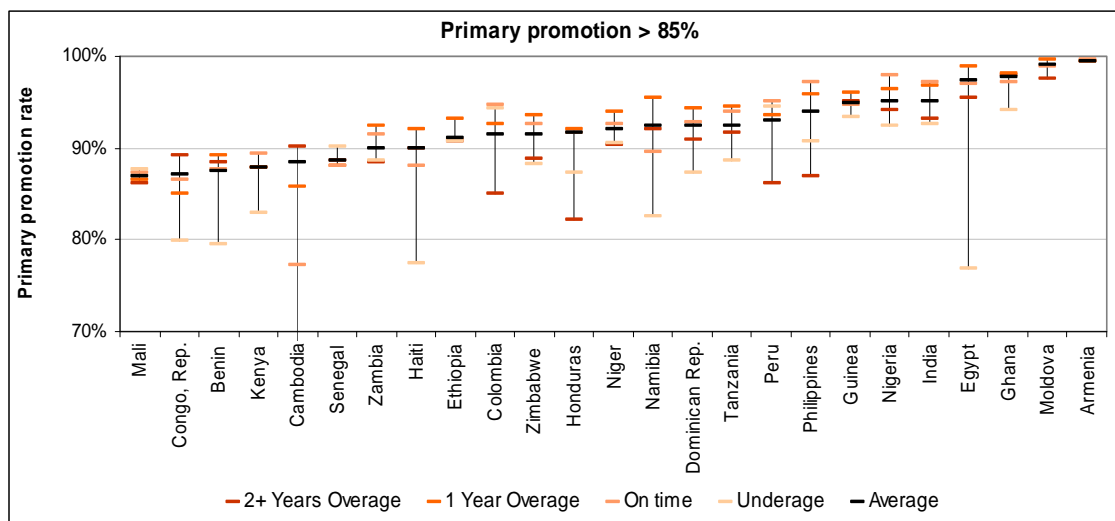

Average primary promotion rates range from 67% in Malawi and Rwanda to 99% in Moldova and Armenia. There are 7 countries with promotion rates of 95% or higher; 10 with average promotion rates of 85% and lower. In the countries with lower overall promotion rates, there is a greater range of promotion rates between the different relative age groups.

Among the ten countries with the lowest overall primary promotion rates (Malawi -- Lesotho on the figure), there is a clear positive relationship

between relative age and promotion rate: in nine of the ten countries, the older the pupils, the higher the promotion rates. The exception is Nicaragua, where the pattern is inverted: the younger the pupils, the higher the promotion rates.

In the 25 countries with overall primary promotion rates of above 85%, promotion patterns among the relative age groups are less distinct. Figure 6 zooms in on these countries. In 9 of these 25 countries, pupils 2+ years overage have lower promotion rates than underage pupils; in the remainder, the reverse is true. In Colombia, Honduras, Peru, and the Philippines, the promotion rates of pupils 2+ years overage are significantly lower than those of other groups.

Figure 6. Promotion rates by relative age group in primary for the 25 countries with average primary promotion rates higher than 85%.

At the secondary level, the oldest pupils 2+ years overage consistently have lower promotion rates than the underage, on-time, and one year overage pupils. In 27 of the 35 countries, pupils 2+ years overage have the lowest promotion rates. There are a few exceptions: in Benin, Cambodia, and Senegal the overage pupils

perform well compared to other relative age groups.

In countries with relatively high average secondary promotion rates, the on-time and one year overage pupils' promotion rates are very close, whereas the underage pupils and those 2+ years overage are further away from the average.

Survival rates by relative age

Another key measure of success is pupils' ability to progress through the school system and reach higher grades – the survival rate. The survival rate is largely determined by cumulative dropout rates, although repetition plays a secondary role, because each time pupils repeat there is a chance they will drop out after the repetition.

The survival rate can be calculated based on promotion, repetition, and dropout rates for each of the four relative age groups. The survival rates are somewhat artificial because they are not the survival rates of cohorts of pupils who start school in a particular relative age group; they are simply calculated based on the promotion, repetition, and dropout rates for each relative age group. On-time pupils can move to being one or 2+ years overage if they repeat; and one year overage pupils can move to being 2+ years overage if they repeat, thus shifting from one survival curve to another. That said, the survival rates remain a useful summary indicator of the performance of the relative age groups.

The top graph, survival to grade 5, shows relatively high survival rates in all countries— notably higher than the survival rates from administrative data in some countries, such as Uganda—in particular for the on-time and one year overage pupils. Both of these groups have very similar survival rates, except in Nicaragua, where the one year overage pupils have lower survival. The age gap of one year has little effect on survival rates.

Figure 7 shows the survival rates to grade 5 and to the middle of secondary school (grade 9) for three relative age groups: on-time, one year overage, and 2+ years overage. At the highest grades of secondary school, 10-13, a comparison is not possible in many countries because there are too few on-time and one year overage pupils to calculate the flows. The underage group is not shown in the figure because there are too few data points. Country-specific graphs with survival rates by grade are shown in Annex 2.

The top graph, survival to grade 5, shows relatively high survival rates in all countries⁷— notably higher than the survival rates from administrative data in some countries, such as Uganda—in particular for the on-time and one year overage pupils. Both of these groups have very similar survival rates, except in Nicaragua, where the one year overage pupils have lower survival. The age gap of one year has little effect on survival rates.

Pupils 2+ years overage fare worse than the two younger groups. Their survival rates are up to 20 percentage points lower, even 37 percentage points lower in the case of Nicaragua.

By grade 9, the survival differences between the relative age groups are much stronger. One year overage pupils do worse than on-time pupils in most countries, although there are a few exceptions. Pupils 2+ years overage, however, clearly have even lower performance. In Nicaragua, almost no pupils 2+ years overage reach grade 9; in many countries only half do so, compared to 60-80% for the on-time and one year overage pupils in most countries. The graphs in Annex 2 show that much of the loss occurs at the transition from primary to (lower) secondary school, although at each successive grade, the 2+ overage pupils fare worse.

Repetition and dropout by grade

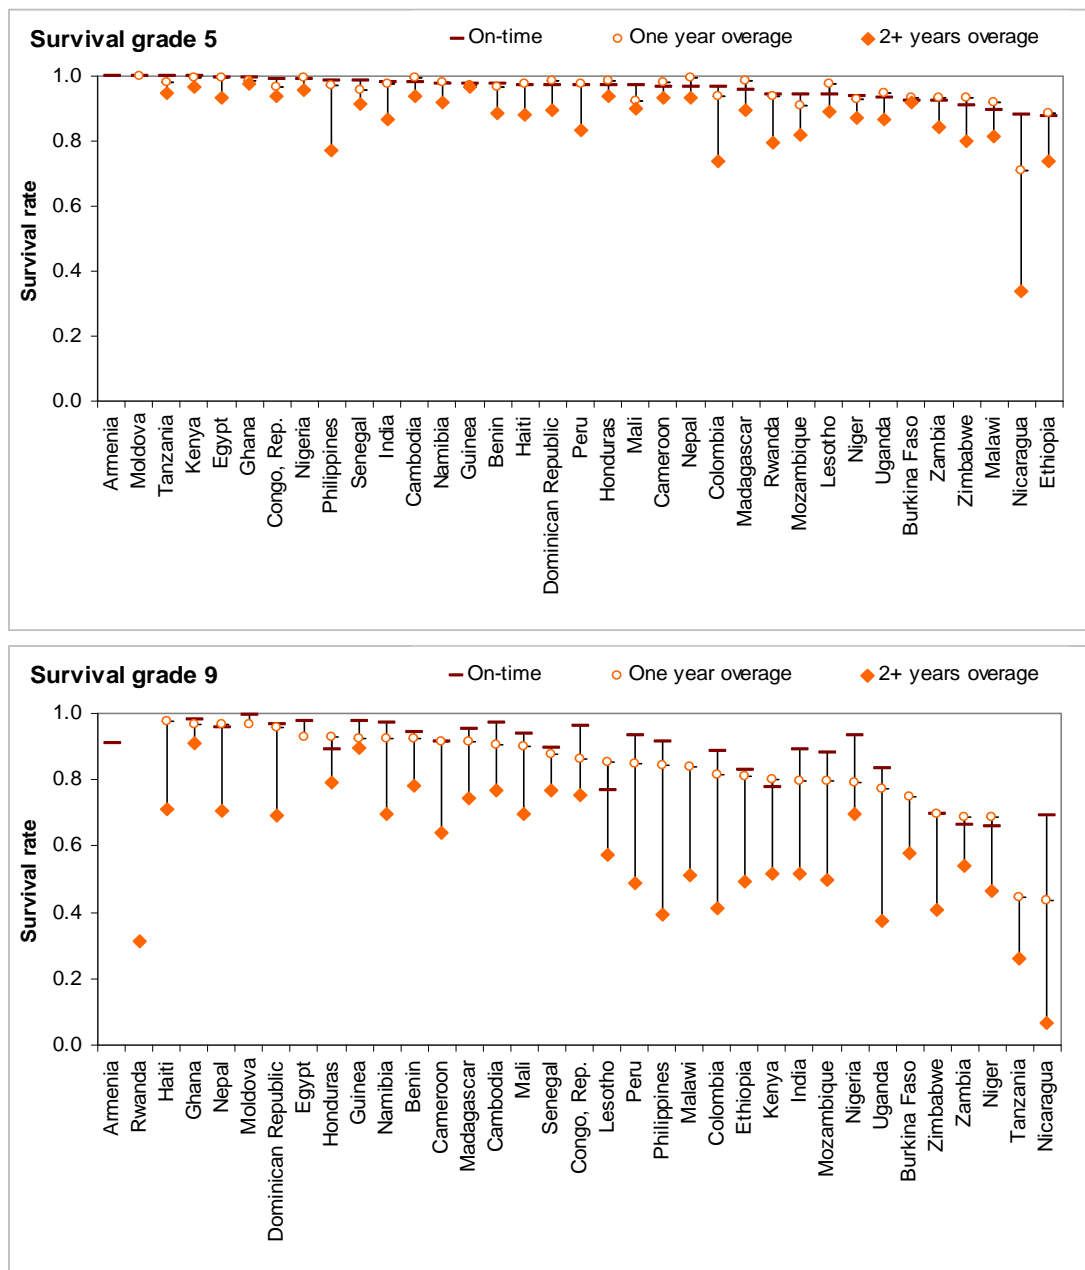

When pupils are not promoted to the next grade or level, they must, by definition, either repeat the same grade or drop out of school.⁸ It is therefore possible to analyze non-promotion in terms of repetition and dropout rates. This section presents grade-specific and age-specific repetition and dropout rates, as well as some

⁷ Readers who are familiar with the survival rates calculated from administrative data and published, for example, by UIS, will note that the survival rates calculated from DHS data are significantly higher for some countries, such as Uganda. A partial explanation may be that in the administrative data, repetition rates are under-reported, causing a lower estimate of survival. It is beyond the scope of this paper to analyze exactly what causes the differences, but again, the reader should be cognizant of the fact that these differences exist and may influence the validity of the results.

⁸ In other words, 'Repetition Rate + Promotion Rate + Dropout Rate = 100%'.

general findings on repetition and dropout that are not necessarily associated with relative age groups.

Figure 7. Survival rates to grade 5 (top graph) and grade 9 (bottom graph) for three relative age groups: on-time, one year overage, and 2+ years overage. The survival to grade 5 is arranged in descending order of on-time survival; the survival to grade 9 in order of one year overage survival because there is no on-time survival data for five countries.

Recall that in primary school, when promotion rates are low, overage pupils generally have higher promotion rates than younger pupils; when promotion rates are above 85% there is no pattern; and in secondary school, overage pupils generally have lower promotion rates than younger pupils. Figure 3 presents country-specific repetition and dropout rates in detail, by grade and relative age group in *dropout and repetition graphs*. In these graphs, grades are given along the vertical axis; repetition rates are along the horizontal axis to the right, and dropout rates are to the left, both increasing away from the central axis. Blue lines between school grades represent transitions between school levels (primary to lower-secondary; lower- to upper-secondary; end of secondary). The repetition and dropout rates for each relative age group are indicated by the same orange colors as in Figure 5. When a repetition or dropout rate for a particular age group is not shown, it is because the sample size for that group was too small.

Though different countries exhibit unique trends in repetition and dropout rates across the various relative age groups, some general trends can be observed:

- Dropouts are more likely to be older pupils; repeaters are more likely to be younger pupils.
- Certain school systems have a clear bias towards repetition rather than dropping out. In Benin for example, repetition rates far exceed dropout rates for all relative age groups and at all grade levels.
- In many countries, repetition rates are highest in the first grade of primary, and are sometimes also high the last grades of a level. Within each grade, successively younger groups have successively high repetition rates. This is especially true in grade 1. One can imagine that in some countries, high repetition rates in grade 1 are the result of extremely crowded first grades where fewer pupils master the skills needed to be promoted. Additionally, particularly high repetition rates among underage pupils

in first grade suggest that parents are sending their underage children to school early as a replacement for kindergarten or early childhood care.

- In many countries, dropout rates increase with grade and school level and spike at grades preceding the transition to a next level (the last grades of primary and lower secondary). This pattern is especially pronounced for older pupils. Moreover, the older the pupils within each grade, the higher the dropout rates. The spike in dropout or repetition rates at transition grades suggests that there are higher barriers to success in these grades. Obstacles may include an exam or a fee that must be paid before the student can progress to the next level.

The repetition and dropout patterns illustrated in the graphs explain some of the changes in the composition of relative age groups from primary to secondary or from the first grade of primary to the first grade of secondary, shown in Figure 2 and Figure 3. In India, for example, high dropout rates among overage pupils at the primary level reduce the number of overage pupils in the system, while low repetition rates among younger age groups ensure that the number of overage pupils is not replenished – as a result, the proportion of overage pupils in that country falls. In Burkina Faso, a spike in repetition rates at the last grade of primary (grade 6) that is especially pronounced among pupils who are overage and on-time helps explain the relatively large increase in overage pupils illustrated in Figure 3. In Moldova, where repetition and dropout rates are very low until well into lower secondary, there is little observed change in the proportion of overage pupils. In the Philippines, there is also little change in the proportion of overage pupils from primary to secondary school, only in this case it is because the high repetition rates in the earliest levels of primary are offset by high dropout rates among overage pupils at the highest grade of primary.

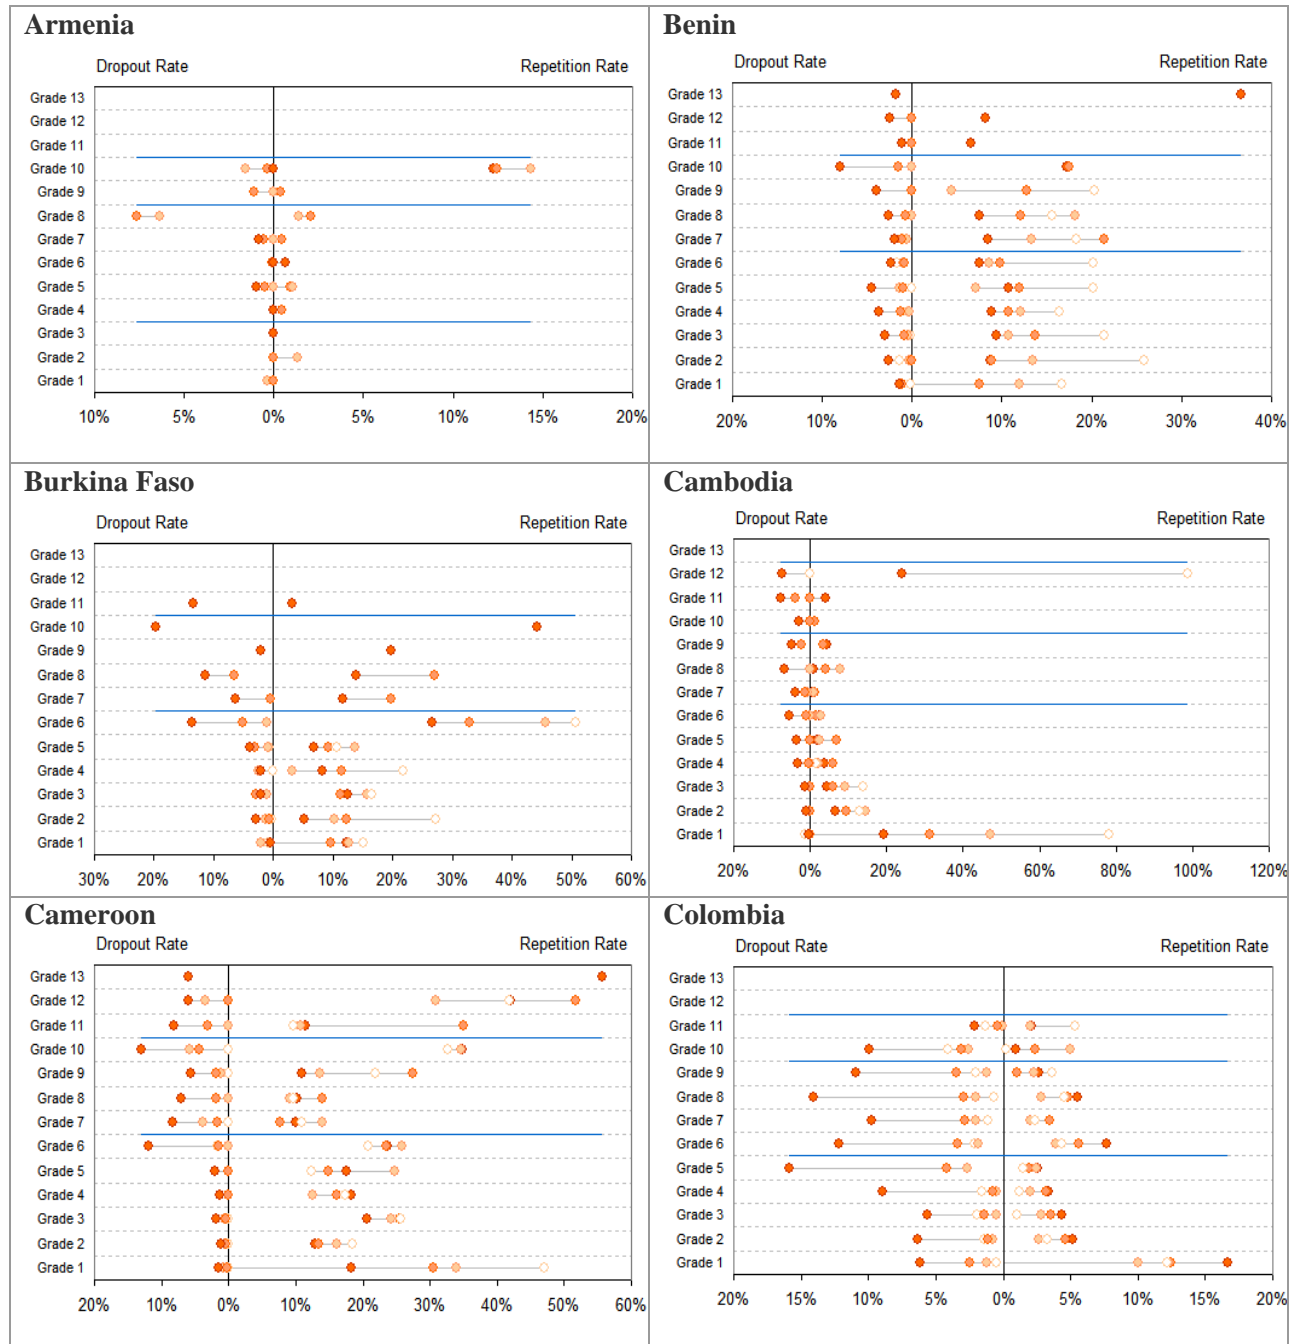

Figure 8 continued.

Transition grades: the first and last grades of primary

This section analyzes the repetition and dropout rates in two ‘transition grades’ that pupils are most likely to encounter – the first grade of primary and the last grade of primary.⁹ Juxtaposing age-specific repetition and dropout

rates for these grades exposes some exceptionally high inefficiencies occurring at these grades for particular groups. Through pinpointing specific inefficiencies, it should be easier to decide where focused interventions are needed. The section first discusses repetition in the first and last grade of primary, and then discusses dropout rates.

⁹ Because the last grade of primary can be a different grade in each country, specific grade numbers are not referenced.

Figure 9 presents repetition rates for each relative age group for the first grade (top graph), average primary across all grades (middle graph), and the last grade of primary (bottom graph). In all three graphs, countries are ranged in order of increasing average primary promotion rate.

In most countries, repetition rates at the first grade of primary are higher than average primary repetition rates, and repetition rates at the last grade of primary are lower than average primary rates. This pattern extends across relative age groups; repetition for each particular age group is higher in the first grade of primary than the average primary repetition for each age group. There are six countries with the opposite pattern: low repetition rates in first grade and high rates in the last grade: Burkina Faso, Mali, Senegal, Niger, Guinea, and Egypt. It is notable that all these countries are in Africa, and many in the same Western region with a Francophone colonial history. The proximity and shared history may be related to the unique pattern in these countries.

Variation in repetition rates across age groups is highest in countries where overall repetition rates are highest and also in the grades where repetition is highest: in first grade for most countries, and in the last grade of primary for the six exceptional countries mentioned above. In Cambodia, Haiti, Lesotho, and Madagascar, the margin between repetition for underage pupils and repetition for on-time pupils exceeds 20

percentage points. For the last grade of primary in many countries, where repetition rates are low, the repetition rates between age groups vary little – often one to two percentage points.

In general, as observed earlier in the discussion of the dropout and repetition graphs in Figure 8, the younger the pupils are, the higher the repetition rates. This exact pattern is found in 21 of the 35 countries, but in another eight, this general pattern is altered only slightly with two of the four age groups switched. In Columbia, Honduras and Peru (all in Latin America) the exact opposite pattern is observed – the youngest pupils have the lowest repetition rates and the oldest pupils had the highest rates. In three countries, the pattern is mixed.

Underage pupils in grade 1 are of particular note, because with their substantially higher repetition rates, they are significant contributors to overall grade 1 repetition rates.

Among countries where underage pupils make up a large proportion of the pupils in first grade and underage pupils have unusually high repetition rates, repetition among underage pupils can account for a large portion of overall repetition in the grade. In Cameroon for example, where 26% of grade 1 pupils are underage and 47% of underage pupils in grade 1 repeat the grade, 11.3% all grade 1 pupils are underage pupils who are repeating.

Figure 9. Repetition rates for each relative age group at the first grade of primary, primary, and the last grade of primary.

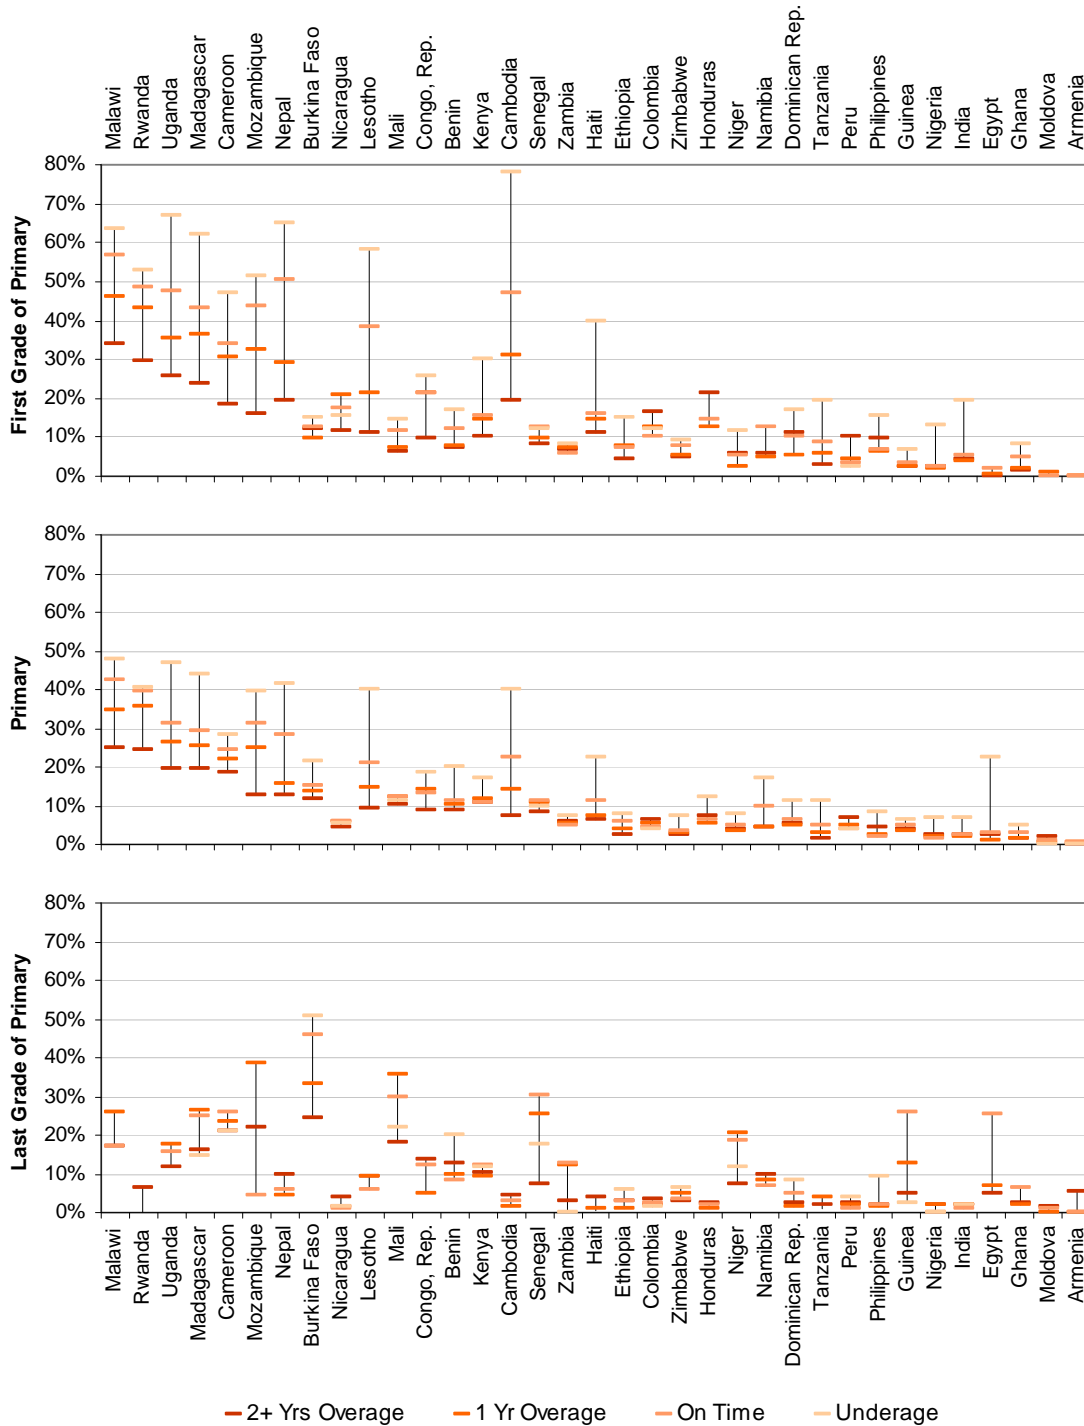

Figure 10. Underage pupils and underage repeaters as a percentage of pupils in the first grade of primary.

Figure 10 shows the magnitude of this problem across countries. The graph shows the percentage of grade one pupils who are underage (total column height), the percentage of grade one pupils who are underage repeaters (filled in portion of column), and overall grade 1 repetition (black bar). In Cameroon, Madagascar, Malawi, and Uganda, underage pupils make up the largest proportion of grade 1 pupils *and* underage pupils have high repetition rates. In India, Niger, and Nigeria, where the overall repetition is relatively low, nearly all of the pupils who repeat are underage.

presents dropout rates for each relative age group for the first grade (top graph), average primary across all grades (middle graph), and the last grade of primary (bottom graph). The countries are arranged as in Figure 10, in order of increasing average primary promotion rate.

For dropout rates, the patterns are almost the exact mirror of the observations for repetition. Whereas repetition rates are higher in the first grade of primary and lower in the last grade of primary, the inverse is true for dropout rates:

dropout rates for first grade are lower than average dropout rates; dropout rates for the last grade of primary high. This pattern extends across all relative age groups with few notable exceptions.

For dropout rates, there is a strong *positive* relationship between relative age and dropout rate (the opposite of the relationship for repetition). At the last grade of primary, pupils 2+ years overage have the highest dropout rates; pupils one year overage have the next highest dropout rates; on-time pupils have the second lowest dropout rates and underage pupils have the lowest dropout rates. This hierarchy is the general pattern observed in the sample countries.

As with repetition, variation in dropout rates between relative age groups is the highest where dropout rates are high. In the last grade of primary, dropout rates for pupils 2+ years overage exceed those for the group with the next highest rate by a large margin. In Uganda, Nicaragua, Zimbabwe, Peru, and the Philippines, this margin exceeds 15 percentage points.

Figure 11. Dropout rates for each relative age group at the first grade of primary, primary, and the last grade of primary.

CONCLUSION: OPPORTUNITIES FOR TARGETED POLICY INTERVENTION

There is wide variation of pupils' ages within grades in many developing countries with some pupils being underage, some on-time, and others one, two or more years overage. Pupils of different ages face unique age-specific challenges, even when they are enrolled in the same grade. It may be that the variation of ages has classroom-wide effects on all the pupils, but it was not possible to investigate that question here; rather this study focuses on the relative performance—in terms of promotion, repetition, and dropout—of pupils by age. Extractions from recent Demographic and Health Surveys from 2000-06 provide the age-specific pupils and flows.

The study finds that in the early grades of primary school, promotion rates are positively correlated with age; the overage pupils generally have the highest promotion rates, and underage pupils the lowest. There may be multiple explanations for this: overage pupils may be repeaters who are seeing material for a second time; they may be highly motivated in the early grades; or teachers may promote them out of sympathy.

Underage pupils in some countries have much higher repetition rates in the first grade of school than on-time and older pupils. This finding suggests that there is an unmet need for early childhood education in these countries: parents may be utilizing first grade as a replacement for nonexistent or insufficient kindergarten and pre-school facilities. Of the 35 countries included in this study, the countries where this effect appears strongest are: Nicaragua, India, Uganda, Malawi, Madagascar, and Cameroon. In these countries, there may be an urgent need to expand age-appropriate facilities for these young children.

Once they reach the upper grades of primary school and secondary school, overage pupils encounter stronger pressures to drop out. In

many countries the promotion and survival rates of overage pupils in these grades are lower, and in most countries the dropout rates higher, than those of on-time or underage pupils. Dropout rates of overage pupils gradually increase throughout primary school, and in many countries peak at the last grade of primary (the transition to secondary school). As the older pupils reach these higher grades, they are also reaching ages where they must find work, get married, or otherwise take on adult responsibilities. It may be that the higher dropout rates they experience are simply a function of age, rather than the effect of being overage within the grade. That said, the underperformance of overage pupils at higher grades is particularly noteworthy when compared to their above-average performance in lower grades.

There is a need to develop focused programs for this group of students to encourage them to continue school at higher levels. The programs should be based on knowledge of the particular obstacles faced by these pupils in upper grades. It is beyond the scope of this study to identify what these obstacles are, although a separate analysis is possible, using the surveys with the question on the "Reasons you left school", and comparing the reasons overage pupils drop out to why on-time or underage pupils drop out.

A deepened understanding the nature of the pressures faced by pupils of different age groups, and the manner in which these pressures are amplified or diminished at various points in their educational careers, can be an invaluable tool for policymakers. Through carefully-targeted interventions designed to address the specific needs of a single age group at a barrier grade, it may be possible to achieve improvements in the internal efficiency of a school system.

DEFINITIONS

- Children of primary school age.** The total number of children who are of the ages in the primary school age interval.
- Children of secondary school age.** The total number of children who are of the ages in the secondary school age interval.
- Dropout rate grade X.** Pupils who were not attending school in the current year but *did* attend grade X in the previous year, divided by the pupils who attended grade X in the previous year. This is a broad definition of dropouts, and includes both 1) pupils who dropped out without completing the grade or level they most recently attended, and 2) pupils who completed a grade or level but did not move on the next. With this definition, pupils who quit school at one of the transition grades, such as the end of primary, basic, mandatory, or lower secondary school, are counted as dropouts – peak dropout rates at these points indicate barriers that prevent pupils from moving on to the next level. The study does not extend past the last grade of secondary and all pupils who report having completed the last grade of secondary are classified as ‘promoted’.
- Gross intake rate (GIR).** The number of new first grade entrants regardless of age, divided by the number of children who are of the official school start age.
- Length of primary school.** The number of grades included in primary school, taken from the UIS data system for level ISCED1 for enrolment rates, and the national definitions for the attendance rates.
- Length of secondary school.** The number of grades included in secondary school, taken from the UIS data system for level ISCED2 for enrolment rates, and the national definitions for the attendance rates.

Official age to start school. Official age at which children should enter first grade of primary school.

On-time. The pupil's age for the previous year is equal to the official age for the grade they reported attending during the previous year.

One year overage. The pupil's age for the previous year is one year higher than the official age for grade they reported attending during the previous year.

Primary age-specific attendance rates. The total number of children who said they were attending primary school, expressed as a percentage of the specific age populations.

Primary school age. The age between the official age to start school and the official age to end primary school (official start age plus number of grades in primary school).

Promotion rate grade X. Pupils who were attending grade X+1 or higher in the current year *and* who attended grade X in the previous year, divided by the pupils who were attending grade X in the previous year. This category includes pupils who were reported to have advanced one *or more* grades from the first year to the next.

Promotion rate last grade of secondary school. Pupils who were attending the last grade of secondary school in the previous year *and* report currently having attained "complete secondary", divided by the pupils who were attending the last grade of secondary school in the previous year. Because the study analyzes the pupils who attended school in the previous year for each dataset, *new entrants* to the school system in the present year are not considered in this study. A pupil would be classified as a new entrant if they reported not having attended school in the previous year, but did attend school in current year.

Reconstructed cohort method. A more pertinent and commonly used method that places less demand on the availability of detailed data over time. To apply this method, data on enrolment by grade for two consecutive years and on repeaters by grade from the first to second year will be sufficient to enable the estimation of three main flow rates: promotion, repetition and dropout. Once obtained, these rates may be analyzed first of all by grade to study the patterns of repetition and dropout. Then, they are used in a reconstructed pupil-cohort flow to derive other indicators of internal efficiency.

Relative age of pupils. Refers to how many years the pupils' age departs from the official age for their grade. The official ages for each grade are based on UNESCO Institute for Statistics (UIS) definitions.

Repetition rate grade X. Pupils who were attending grade X or a lower grade in the current year *and* who attended grade X in the previous year, divided by the pupils who were attending grade X in the previous year.

School survival to grade 5. Calculated using the reconstructed cohort method based on promotion, repetition, and dropout rates up to grade 5. It is primarily determined by dropout rates; secondarily by repetition. Promotion, repetition and dropout can be calculated from DHS data on attendance by grade in the present and the previous year. The promotion rate for grade n is the percent of children in grade n+1 in the present year, who were in school in grade n in the previous year. The repetition rate is the percent of children in grade n in the present year, which was also in grade n in the previous year. The dropout rate for grade n is children who were in grade n in the previous year, but are not attending school in the present year.

Secondary age-specific attendance rates. The total number of children who said they were

attending secondary school, expressed as a percentage of the specific age populations.

Secondary school age. The age between the official start age for secondary (the last official age of primary school plus one), and official age to end secondary school (the official start age for secondary plus the number of grades secondary school).

Underage. The pupil's age for the previous year is lower than the official age for the grade they reported attending during the previous year.

2+ years overage. The pupil's age for the previous year is two or more years higher than the official age for grade they reported attending during the previous year. Note that this definition of overage is *overage for grade*, as opposed the definition of overage commonly used by UIS and GMR, where the overage pupils in primary are those who are older than the official primary school age range.

ACKNOWLEDGEMENT

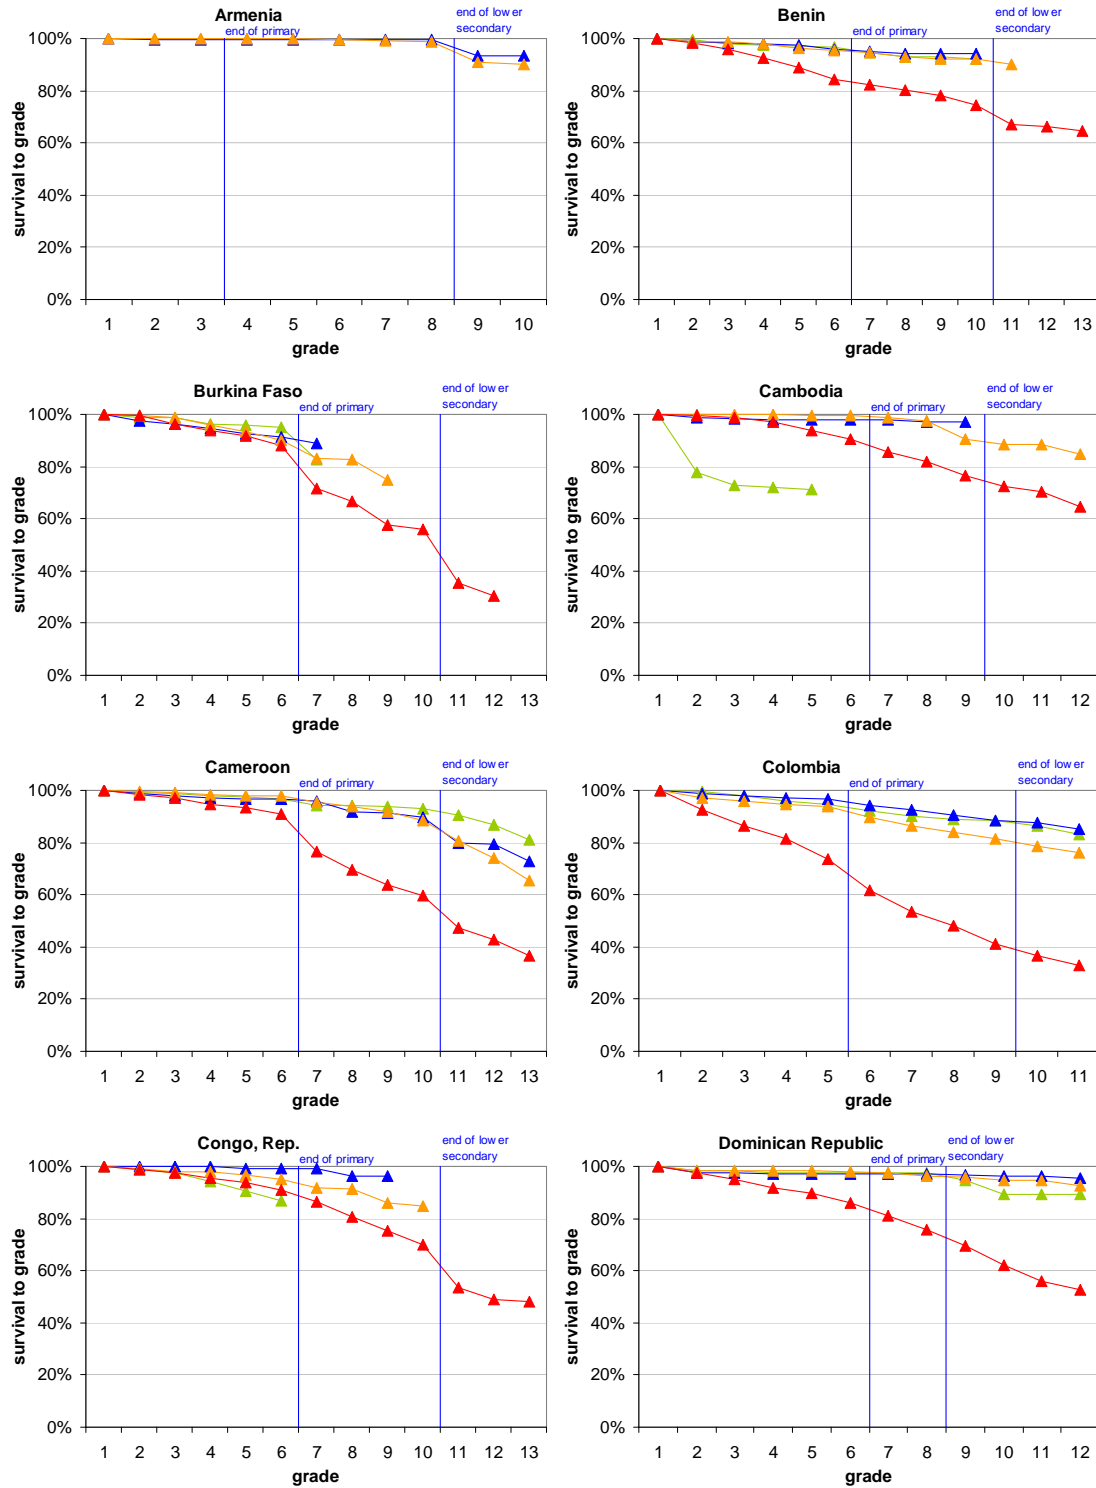

This report has been prepared by the Education Policy and Data Center (EPDC) staff, Annabette Wils, Sarah Oliver, and Ben Sylla, and reviewed by George Ingram. The first draft of this paper was prepared as one of a series of reports the EPDC provided as background for the 2009 EFA Global Monitoring Report. The EPDC team is grateful to the GMR team for excellent guidance and commentary and for the collegial spirit in which this work was conducted. However, the views presented in this report are those of the EPDC only and do not necessarily reflect those of the Global Monitoring Report or any other organization.
